Appendix D
Technical Memorandum

Jacobs

Janicki Environmental, Inc.

Subject	TWA 20TW0002949 P274 Little Manatee River System MFLs Development Support
Attention	Kym Holzwart, Southwest Florida Water Management District
From	Mike Wessel, Janicki Environmental, Inc.
Date	August 18, 2020
Through	James Greco, Jacobs Engineering Group

Dear Kym – On behalf of Janicki Environmental, Inc. and Jacobs Engineering Group, we present this technical memorandum in fulfillment of Task 4.2 of Task Work Order Number 20TW0002949. The deliverables for this task include this technical memorandum, a Microsoft Access database, and a supplemental materials document containing requested descriptive plots and statistics as well as detailed statistical output. We hope that this will serve the District well in its efforts to develop minimum flows for the Little Manatee River. Please feel free to contact us for any reason.

Background:

The objective of this task was to compile water quality and water quantity data and provide analysis of those data with respect to water quality status and trends in the Little Manatee River System. The data collection and technical assistance services will be used by the DISTRICT for consideration of the Water Quality WRV in support of the establishment of MFLs for the Little Manatee River System. The specific objectives of this task were to:

- Update the water quality status and trends analysis (described in Janicki Environmental 2018) by adding additional years of data since 2016 for the five Hillsborough County Environmental Protection Commission sites (112,113, 180, 181, and 182) located on the Little Manatee River from the USGS Little Manatee River at U.S. 301 Near Wimauma gage (Gage #02300500) to the mouth of the river near Shell Point.

- Investigate additional data sources that may be available for locations in the upper portion of the Little Manatee River above the USGS gage.

- Describe any system-specific water body class(es), water body identification numbers (WBIDs), designated use(s), and any impairments, Total Maximum Daily Loads (TMDLs), and Basin Management Action Plans (BMAPs) previously identified by the Florida Department of Environmental Protection (DEP) for the Little Manatee River.

- Provide univariate, summary statistics, plots of spatial and temporal patterns, identification of outliers and data gaps, statistical relationships between identified water quality parameters and flow, and description of potential limitations, and confounding variables in identified statistical relationships.

In 2016, the Southwest Florida Water Management District (District) contracted Janicki Environmental, Inc. through Greenman Pederson, Inc. to provide technical support and recommendations for developing minimum flows for the freshwater and estuarine segments of the Little Manatee River. A draft recommended minimum flow for the freshwater (Upper) segment of the river was first published in 2011 (Hood et al. 2011) and peer reviewed in 2012 (Powell et al. 2012). No recommended minimum flows had been published for the estuarine (Lower) segment of the Little Manatee River in 2016. Janicki Environmental, Inc. provided a reevaluation of the Upper segment and recommendations for the Lower segment of the Little Manatee River in 2018 (Janicki Environmental, Inc. 2018a and 2018b) using data available through 2014. This technical memorandum describes:

- Updates to the analysis described in section 3.3 of Janicki Environmental, Inc. 2018b by including additional data through 2019 and rerunning all descriptive and statistical analysis presented in that section of the report.

- Searching for additional water quality data in the Upper portion of the Little Manatee River (i.e. above US301) and including those data into the master database for delivery.

In order for a station/constituent combination to be considered for analysis it was required to have at least 60 observations. Data with fatal qualifier codes including "Q", "T", "J", "*" and "?" were removed from analysis. The water quality constituents assessed as part of this contract include: salinity, chlorophyll *a*, dissolved oxygen, total nitrogen, ammonia, organic nitrogen, nitrate/nitrite, total phosphorus, orthophosphate, fecal coliform, fluoride, pH, total suspended solids, and turbidity. Accompanying this memorandum as a deliverable is a database of all data identified, as well as a stand-alone document providing supplementary material describing the data, including univariate statistical summaries, identification of potential outliers, and spatial and temporal plots for data meeting the inclusion criteria.

Task 2.2.1 Update of Section 3.3 (Janicki Environmental, Inc. 2018b)

This section focuses on water quality data collected in the estuarine portion of the Little Manatee River from the USGS gage at U.S. Highway 301 to the mouth of the river near Shell Point. The section headings reflect those of the original report.

3.3.1 FDEP Water Quality Classifications and Standards

The Little Manatee River is designated by FDEP as an Outstanding Florida Waterbody, indicating its special significance as a tidal river in Florida. The tidal reaches of rivers in Florida are evaluated based on a narrative standard. The narrative standard is stated under Rule 62-302.530(47)(b), F.A.C.: "*In no case shall nutrient concentrations of a body of water be altered so as to cause an imbalance in natural populations of aquatic flora or fauna*." Each water body also has a "Designated Use" in Florida statue. For Class III waters, the designated use is defined as "*recreation and propagation and maintenance of a healthy, well-balanced population of fish and wildlife*" (Rule 62-302.400, F.A.C.). Impairment according to the State's Impaired Waters Rule 62-303 (F.A.C.) is determined by evaluating two principal water quality constituents: chlorophyll *a* concentrations and dissolved oxygen expressed as percent saturation. The threshold value for chlorophyll is expressed as an annual geometric average of 11µg/l for estuaries and 20 µg/l for freshwater bodies. The dissolved oxygen criteria for marine waters are expressed as; a daily average shall not be below 42% saturation more than 10% of the time and the fresh water standard exceedance is based on a threshold of 38%. Weekly and monthly averages also apply. The state accounts for areas that transition between salt and freshwaters such as the Little Manatee River depending on the conductivity/salinity at the time dissolved oxygen was measured. For example, if the dissolved oxygen of a waterbody is measured within a transitional zone as defined by FDEP, where conductivity is below 4,580 umhos/cm or 2.7 PSU, then the applicable freshwater standard is applied. Conversely, the marine standard is applied if the conductivity exceeds that threshold.

Based on the latest Florida Department of Environmental Protection evaluation (IWR Run 59: July 2020), no mainstem portion of the Little Manatee River is currently listed as impaired for any parameter other than fecal coliform.

3.3.2 Water Quality Status and Trends

The following subsections describe the general water quality status and trends over time for important water quality constituents measured in the estuarine portion of the Little Manatee River based on data collected by the Hillsborough County Environmental Protection Commission (EPC) at five locations within the system. These five locations are provided in Figure 1.

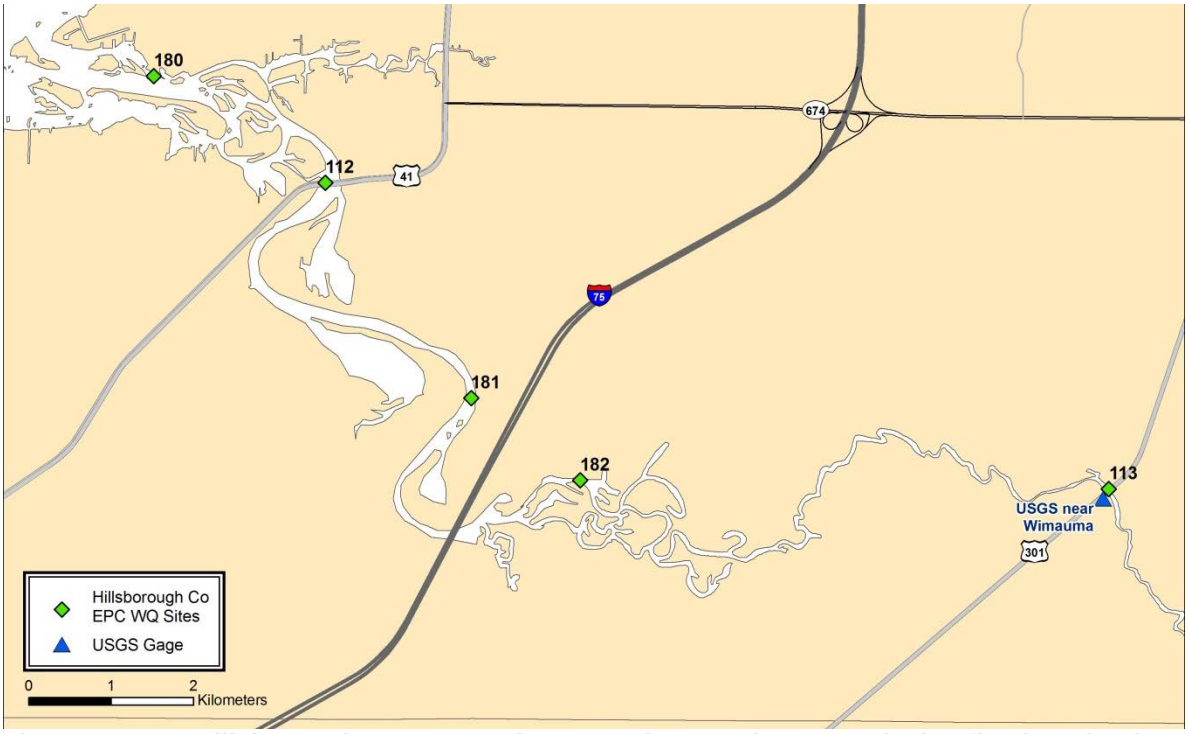

Figure 1. Hillsborough County Environmental Protection Commission fixed station locations in the lower Little Manatee River.

The five EPC fixed stations in Figure 1 are well distributed throughout the Little Manatee River estuary. Station 113 is co-located with the USGS gage near Wimauma (02300500) at the most upstream head of the estuary and has a data record dating back to 1974. Station 112, located near the US41 bridge also has a data record dating back to 1974 while the other three stations were implemented in 2009.

A plot of the salinity distributions at these locations is provided in Figure 2 for reference to the typical physical chemistry of the water quality location. These data are based on a period of record when data were being recorded at all stations (i.e. 2009-2019). These data show the general distribution of the water quality sampling locations along the salinity gradient. The following subsections evaluate the status and trends in other important water quality constituents (other than salinity) using data collected by EPC.

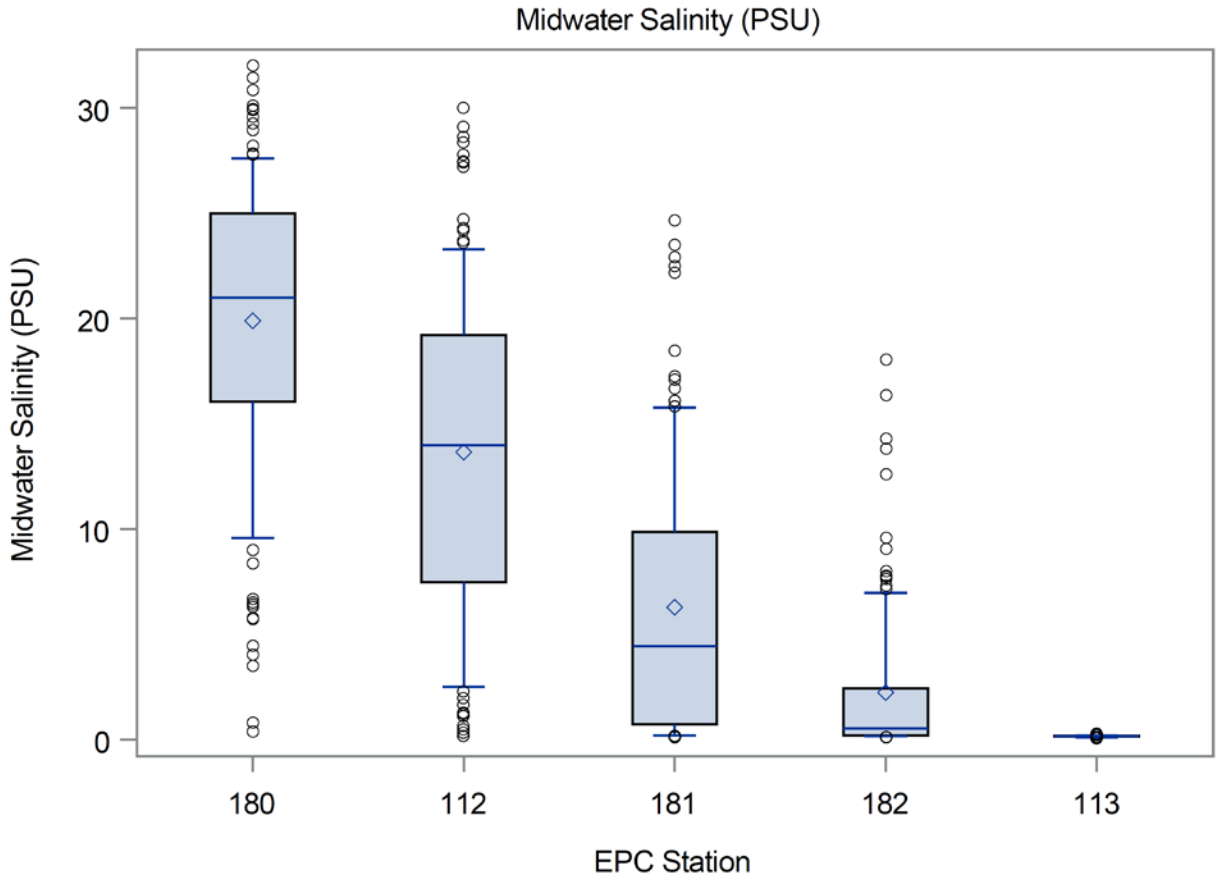

Figure 2. **Salinity distribution at various fixed station locations throughout the estuarine portion of the Little Manatee River (Update of Figure 3-26 in previous report).**

Chlorophyll *a* and Dissolved Oxygen

Given the importance of chlorophyll and dissolved oxygen concentrations as indicators of impairment for tidal rivers, these constituents are evaluated as primary indicators with respect to assessing their status and trends over time. The EPC has historically reported Chlorophyll *a* concentrations using estimates uncorrected for pheophytin and, therefore, the long-term record for chlorophyll was based on these uncorrected values. The station-specific annual distribution of geometric average chlorophyll concentrations is provided in Figure 3. The stations in this plot are oriented from downstream (top) to upstream (bottom). A grey reference line denoting the 11 ug/l threshold is provided within each panel of the plot. The annual averages were generally below the 11 ug/l threshold values, though at stations 181 and 182, where salinity tended to be generally < 10 psu, the averages were more likely to exceed the threshold value. This is typical of the biogeochemistry of tidal rivers where initial mixing of fresh and estuarine waters creates a zone of productivity in the tidal river system.

Dissolved oxygen concentrations (expressed as percent saturation) have been reported since 2002 and tend to be above the 42% threshold for estuarine waters at all stations (Figure 4). The lower “whisker” on the boxplot represents the 10th percentile value which in most years is above the 42% threshold at most stations. Distributions of long-term dissolved oxygen measurements

reported as concentration are provided in Figure 5 which shows inter-annual variation in dissolved oxygen distributions over time. The distributions indicate that dissolved oxygen concentrations are typical of southwest Florida tidal rivers and that hypoxic conditions (i.e. concentrations less than 2 mg/l) are rare at these locations.

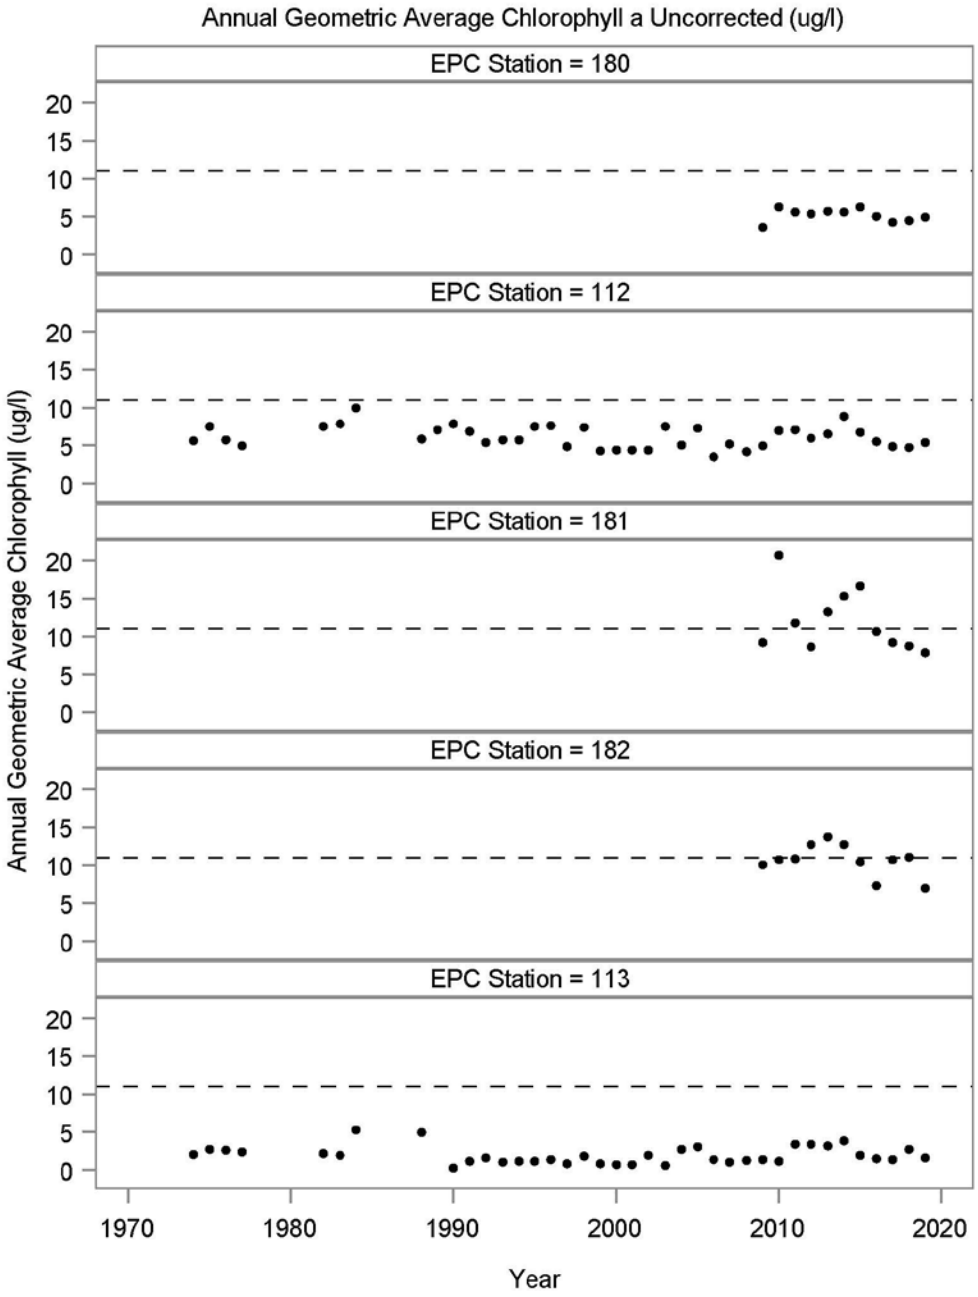

Figure 3. **Annual geometric average chlorophyll concentrations for period of record at each EPC station in the estuarine Little Manatee River. Broken horizontal reference line represents FDEP threshold criteria for evaluating impairment based on narrative standard. (Update of Figure 3-27 in previous report).**

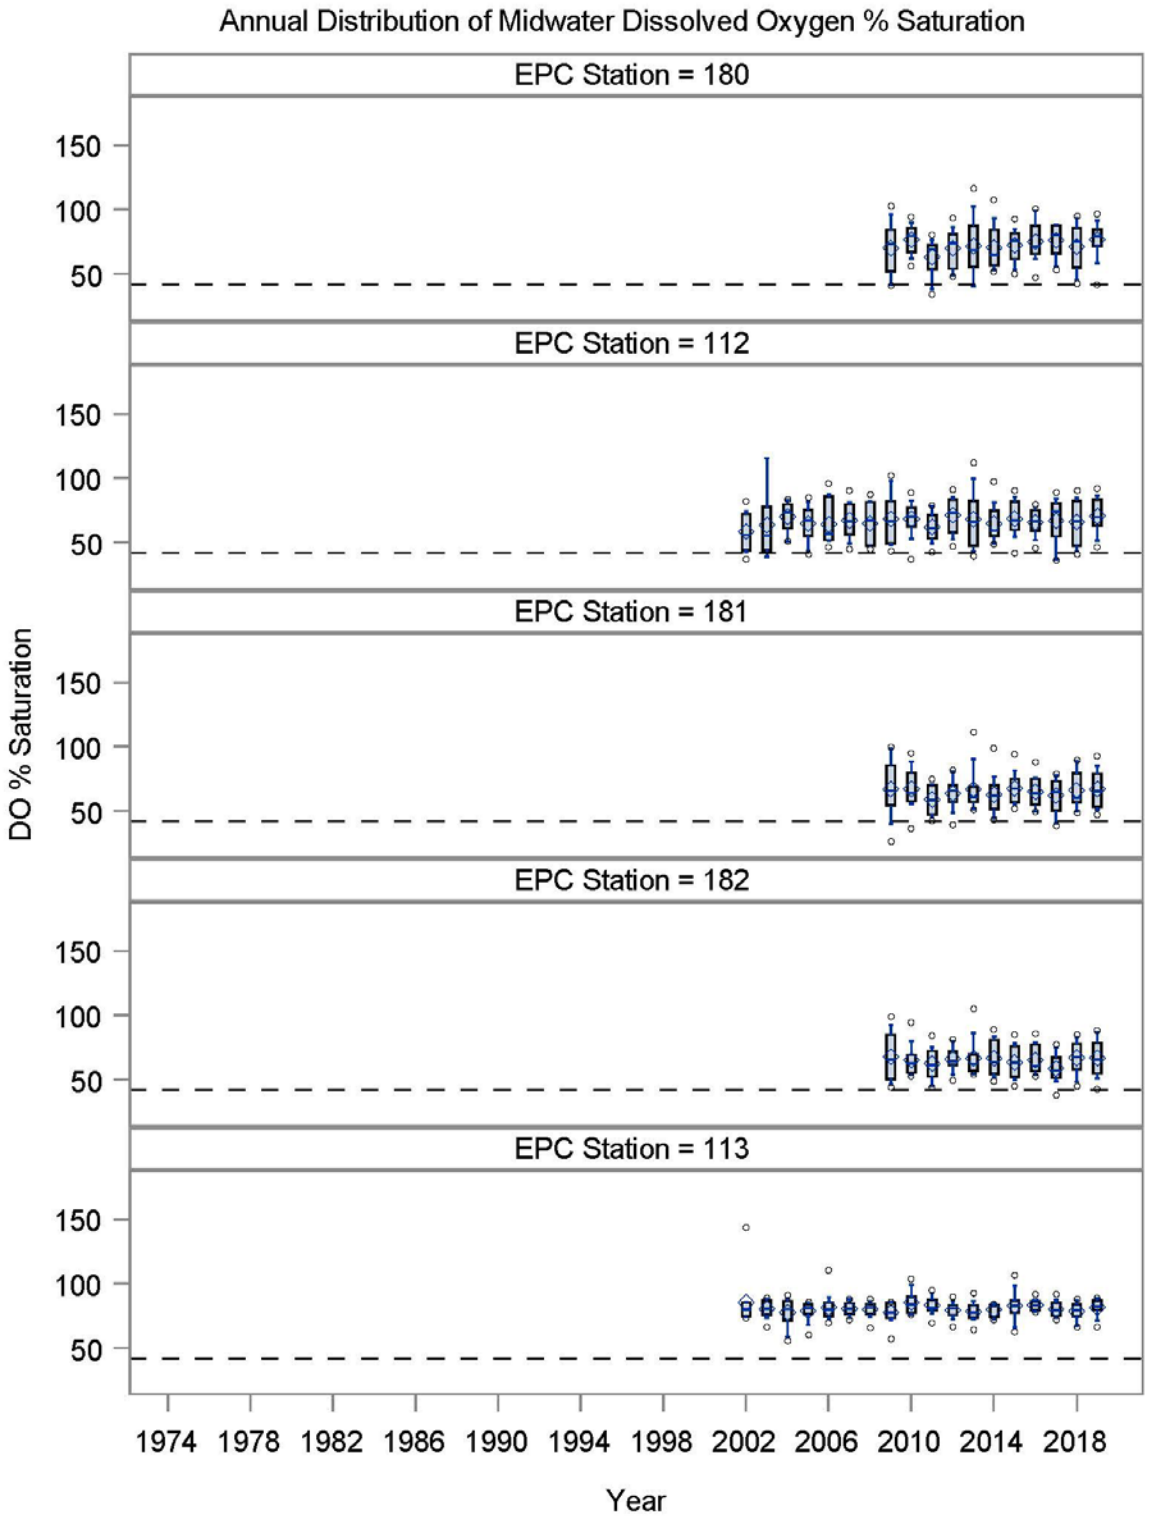

Figure 4. **Annual distribution of dissolved oxygen expressed as percent saturation. Broken horizontal reference line represents FDEP threshold criteria for evaluating impairment based on narrative standard. (Update of Figure 3-28 in previous report).**

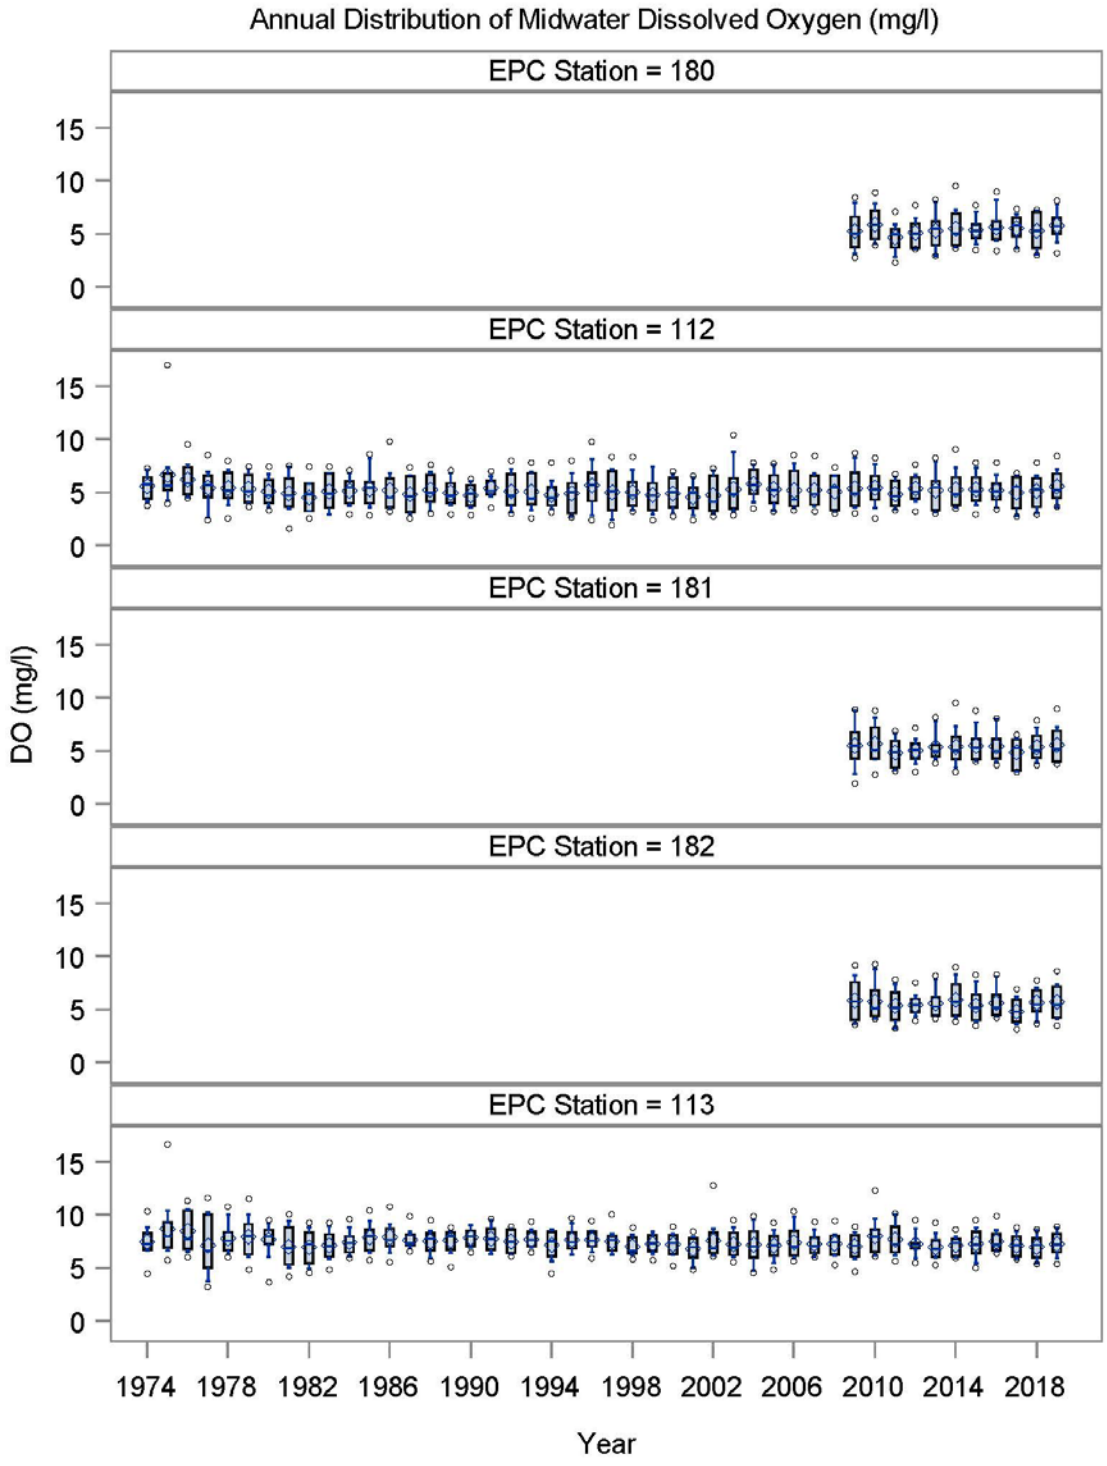

Figure 5 **Annual distribution of midwater dissolved oxygen expressed as concentration. (Update of Figure 3-29 in previous report).**

Trends in water quality over time can provide important information relevant to assessing the status and potential future condition of the waterbody relative to water quality standards. For the freshwater Little Manatee River minimum flows, Hood et al. (2011) evaluated trends in water quality using the Seasonal Kendall Tau Trend Test (Hirsch and Slack 1984) based on data collected by USGS at the Wimauma gage. This nonparametric statistical method tests for a monotonic trend in the data over time but does not provide inference as to what may be causing any detected changes, only that a trend occurred. Hood et al. (2011) elected to partition out the effects of flow on water quality prior to evaluating the data for trend over time. A locally estimated scatterplot smoothing (LOESS) regression was used to predict the effects of flow on water quality and the residuals of that analysis were then used to evaluate the data for a trend over time (after accounting for any trend due to changes in flow over time). Note that USGS no longer collects water quality data at this gage but the EPC station 113 is co-located there. Other District minimum flows reports in tidal rivers (e.g. Lower Hillsborough and Lower Alafia Rivers) did not specifically conduct trend analysis but rather examined the status of water quality constituents as a function of flow. To maintain continuity with the previous reports, this technical memorandum updates previous analysis using the Seasonal Kendall Tau trend test on the water quality data collected by EPC in the estuarine portion of the system both prior to, and after, accounting for the effects of flows. The results are presented in tables in the following subsections by station.

Results of trend tests for chlorophyll *a* and dissolved oxygen are provided in Table 1. Most stations were stable over time for both constituents irrespective of the form of constituent (e.g. DO percent saturation or concentration) or location in the water column. Chlorophyll *a* at station 112 declined over the period of record after accounting for the effects of flow on chlorophyll *a* at this station.

Table 1. Results of Seasonal Kendall Tau trend test for chlorophyll and dissolved oxygen for unadjusted and flow adjusted data. (Update of Table 3-6)

Constituent	Station	Start Year	End Year	# of Samples	Trend Direction	Flow Adjusted Trend Direction
Chlorophyll a (ug/l)	112	1974	2019	403	No Trend	Decreasing
	113	1974	2019	280	No Trend	No Trend

	181	2009	2019	132	No Trend	No Trend
	182	2009	2019	132	No Trend	No Trend

Nitrogen

Nitrogen is a principal nutrient that is fundamental to the success of native flora but can cause adverse effects in the form of phytoplankton blooms if it is found in excess. There are several forms of nitrogen measured by EPC including inorganic forms which are more labile and readily

taken up by plants, and organic forms which principally result from decaying organic matter. Total nitrogen is generally computed as the sum of these organic and inorganic forms. That is, total nitrogen is the sum of organic nitrogen, ammonia and nitrate/nitrite. Most of these forms were either stable or decreasing (improving) over time based on EPC station trend results (Table 2). The only exception was organic nitrogen at station 113 which was found to be increasing over time. While this result suggests the potential for increasing nutrient concentrations, the concentrations do not appear to be resulting in adverse effects to the system based on the results of the chlorophyll concentration analysis described above. Time series plots of total nitrogen and ammonia are provided in Figure 6 and Figure 7, respectively.

Table 2. Results of Seasonal Kendall Tau trend test for nitrogen forms for unadjusted and flow adjusted data. (Update of Table 3-7)

Constituent	Station	Start Year	End Year	# of Samples	Trend Direction	Flow Adjusted Trend Direction
Total Nitrogen (mg/l)	112	1981	2019	457	Decreasing	Decreasing

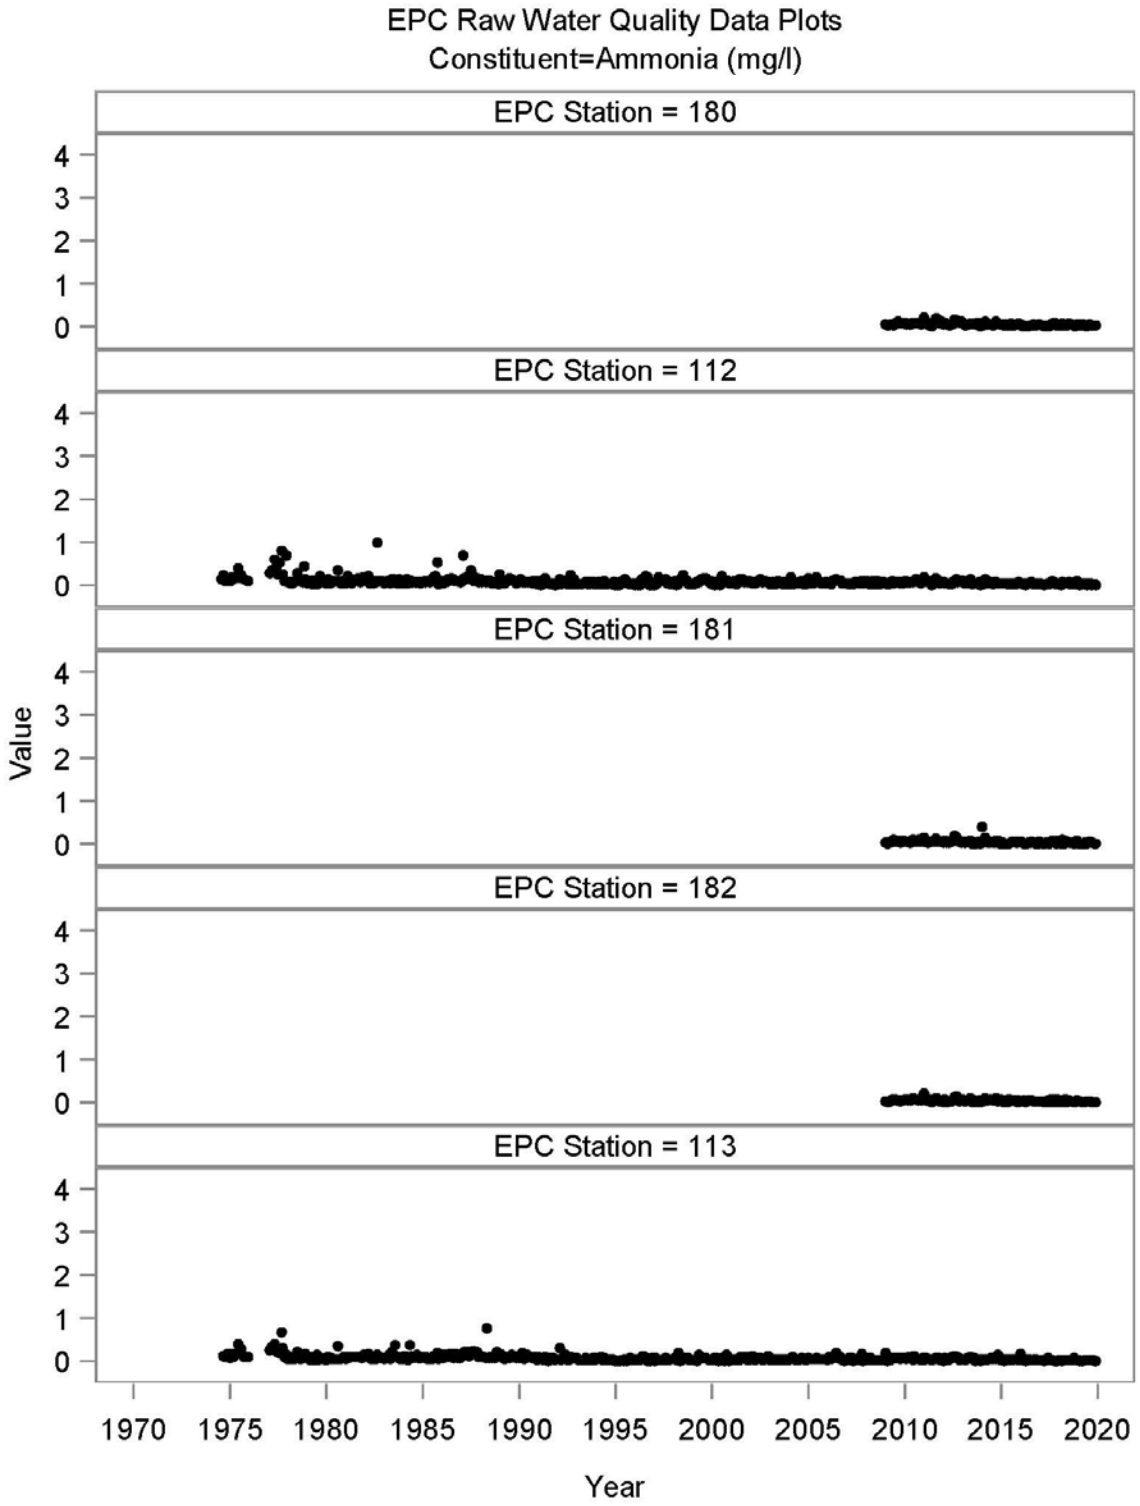

Figure 7. **Timeseries plots of ammonia for each EPC station. (Update of Figure 3-31 in previous report).**

Phosphorus

Phosphorus (P) is an essential nutrient for plants that stimulates early growth. Although P is essential for plant growth, mismanagement can pose a threat to water quality. While the concentration of P is usually sufficiently low in fresh water to be the limiting nutrient, the Little Manatee River resides in the phosphorus-rich "Bone Valley" geological formation and therefore, P is in plentiful supply. Nitrogen is the nutrient that typically limits phytoplankton in Tampa Bay and its tributaries (Fanning and Bell 1985, Vargo et al. 1991, Janicki and Wade 1996, as cited in Flannery et al 2008). Phosphorus is reported by EPC as both orthophosphate and total phosphorus. Results of trend tests suggest phosphorus concentrations at many EPC stations were decreasing (i.e., improving) over time for both constituents (Table 3). Timeseries plots for total phosphorus are provided in Figure 8.

Table 3. Results of Seasonal Kendall Tau trend test for phosphorus forms for unadjusted and flow adjusted data. (Update of Table 3-8)

Constituent	Station	Start Year	End Year	# of Samples	Trend Direction	Flow Adjusted Trend Direction
Total Phosphorus (mg/l)	112	1974	2019	543	Decreasing	Decreasing

	182	2009	2019	132	No Trend	No Trend

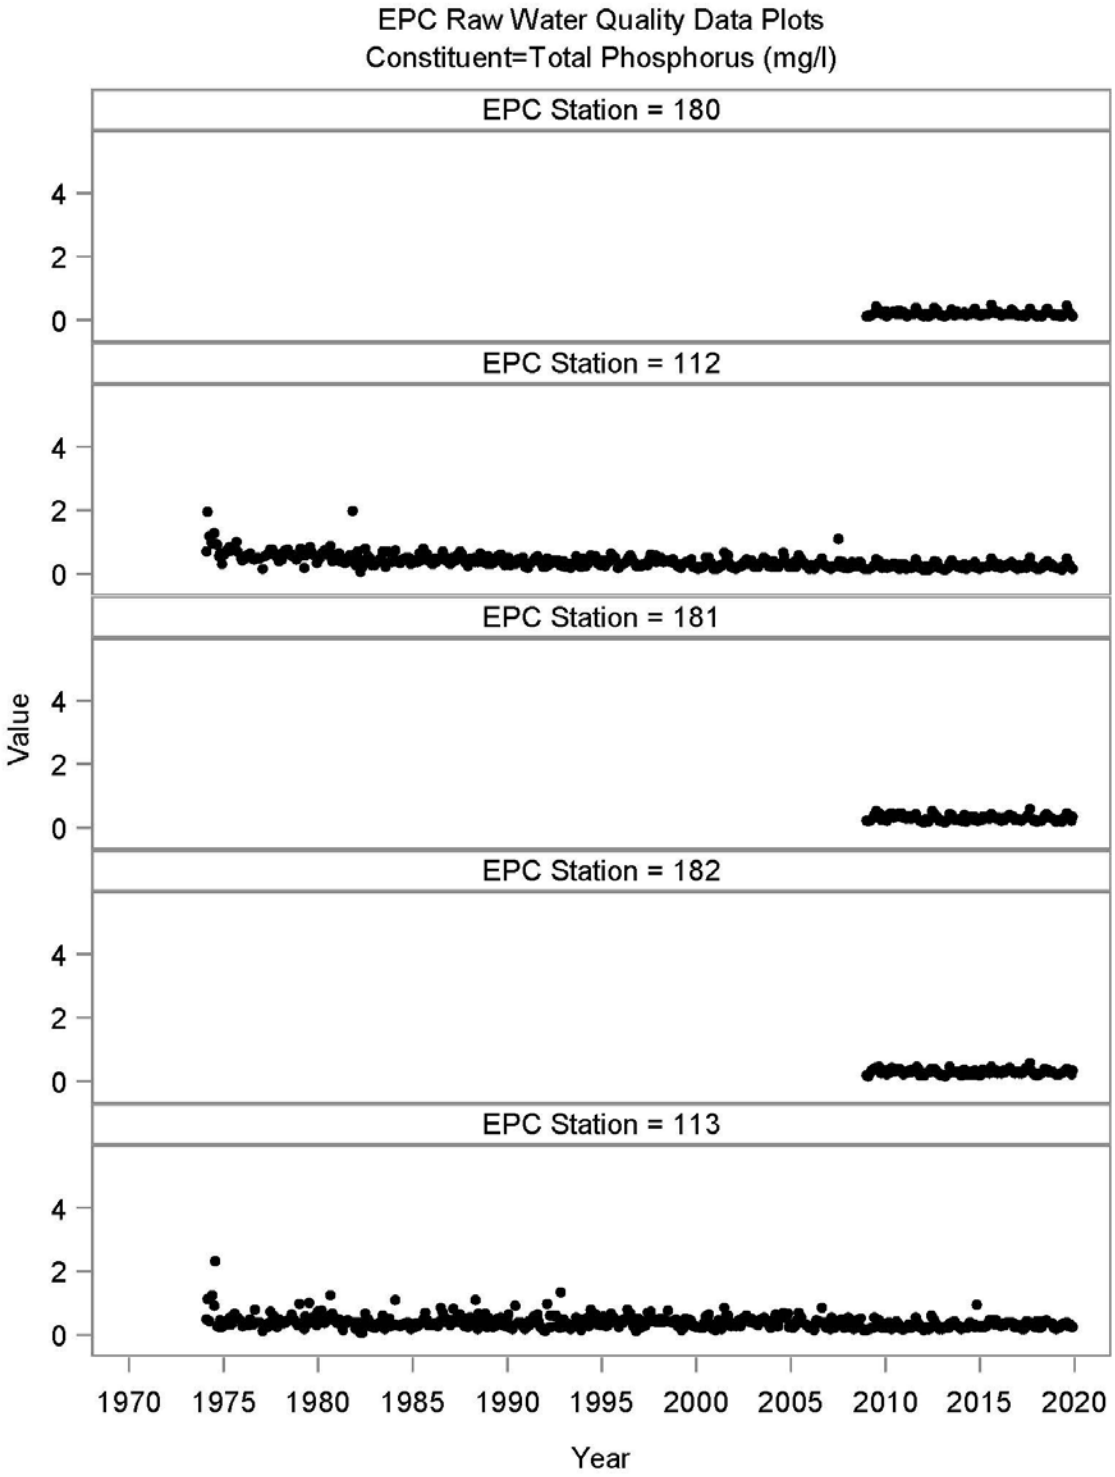

Figure 8. **Timeseries plots of total phosphorus for each EPC station. (Update of Figure 3-32 in previous report).**

Chemical Constituents and Fecal Coliforms

Several other important water quality constituents were evaluated for this project including fecal coliforms, fluoride, pH, total suspended solids and turbidity. The results of trend analysis on these constituents suggest that these water quality parameters were mostly either stable or decreasing (i.e. improving) over time throughout the estuarine portion of the system with the exception of fluoride at stations 113,181, and 182 and pH at stations 112 and 113 (Table 4).

Table 4. Results of Seasonal Kendall Tau trend test for other important water quality constituents for unadjusted and flow adjusted data. (Update of Table 3-9)

Additional Analysis for Sites from US301 Downstream

In addition to the spatial and temporal plots provided above, the District requested a host of descriptive statistics and plots including: univariate summary statistics and identification of potential outliers. These are provided as a separate “supplemental materials” document attached to this memorandum. Additionally, the District requested an assessment of statistical relationships between water quality and flow for each constituent of interest. Linear regression

was performed on natural log transformed data for both flow and the water quality constituent of interest. Linear regression (Zar, 1984) is a common statistical method relating a predictor variable (e.g. flow) to a response variable (e.g. water quality constituent concentration) under a specific set of assumptions; principally that the relationship is linear. Additional assumptions include that the data are normally distributed, independent, and homoscedastic. These attributes are not typical properties of either flows or most common water quality constituents and, to comply with those assumptions, natural log transformations were applied to both the predictor and response variables. To test for seasonal differences in the mean response to flow, a seasonal (monthly) classification term was added to the model using dummy variables to evaluate how different months changed the average response between flows and water quality constituent concentrations. The coefficient of determination describes variance in a water quality constituent attributable to both flow and season when both are significant ($p < 0.05$). Due to limited data availability for most sites, interaction terms were not considered for these models. To evaluate the model fit and potential utility in assessing these water quality relationships, the sign of the slope statistic (i.e., positive or negative), the p value indicating the statistical significance of the slope statistic, and the coefficient of determination (R^2) defining the proportion of variation explained by the model were used to evaluate the resultant linear regression relationships. The following equation depicts the form of the linear regression that was applied.

$$Ln(Y_{ij}) = \beta_0 + \beta_1 * Ln(flow_i) + \beta_2 * season_j + e_{ij}$$

where:
Y = water quality response
β_0= intercept
β_1= slope estimate for the rate of change in Ln(Y)
per unit change in Ln(flow)
β_2 = effect of seasonal covariate defined by month

and the null hypothesis being evaluated:
Ho: $\beta_1 = 0$

The results of these regressions were then summarized in Table 5 below. A zero cell in the table indicates the lack of statistical significance for the flow term for that station. A negative one (-1) indicates a statistically significant inverse relationship between the constituent and flow while a positive one indicates a statistically significant increasing relationship between the constituent and flow. Several constituents had consistent results across stations. Positive relationships with flows across stations included color, orthophosphorus and total organic carbon while consistently decreasing relationships with flow include conductivity, pH, and secchi disk. The remaining constituents exhibited more site specific relationships. Details of the linear regression results for these stations are provided in the supplemental material document associated with this memorandum.

Table 5. **Results of linear regression for the 5 stations in the Lower Little Manatee River based on natural log transformations of both flow and water quality response constituents.**

Task 2.2.2 – Water Quality Stations Upstream of US301

This task involved querying known water quality repositories for data collected upstream of US301 in the Little Manatee River. The area upstream of US301 includes several tributaries and two additional active flow gages as seen in Figure 9 (Figure 2.3 from Janicki Environmental 2018a).

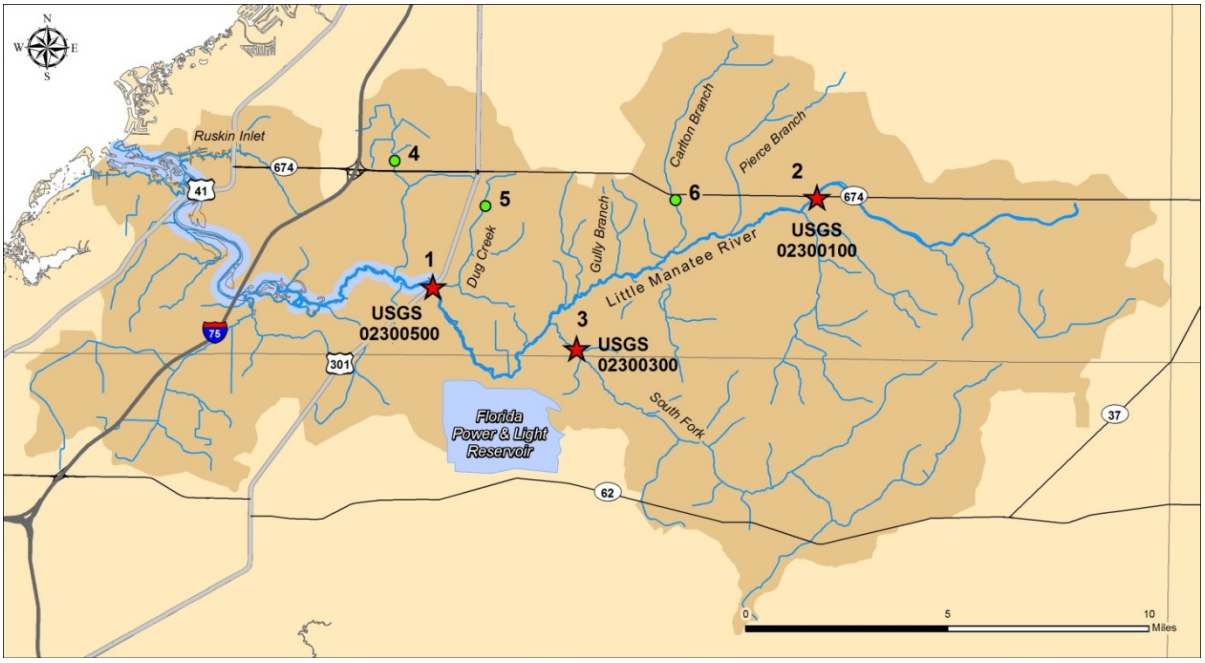

Figure 9. Location of currently active (red stars) and previously operated (green circles) streamflow gages in the Little Manatee River watershed maintained by the USGS (replicated from Hood et. al., 2011).

The EPC and IWR databases were queried to identify routine water quality monitoring sites above US301. Sites were selected if they contained at least 60 observations within their period of record. The identified sites are provided in Table 6. Only the EPC sites (129 and 140) and two Manatee County sites (D1 and D3) are actively sampled. Data for the Manatee County sites are only available through 2017 in the IWR database. A check of the Manatee County Water Atlas (https://manatee.wateratlas.usf.edu/datadownload/SelectStations.aspx) for more recent data suggests no additional data are readily available for these sites though we still consider them active. The remaining stations identified by the query are legacy water quality sampling locations. Therefore, trend test and statistical evaluations were conducted only for these four sites which are identified in Figure 10.

Table 6. Routine water quality sampling stations above US301 in the Little Manatee River with location and period of record of data collection.

Site Id	Site Name	Latitude	Longitude	WBID	First Sample	Most Recent Sample

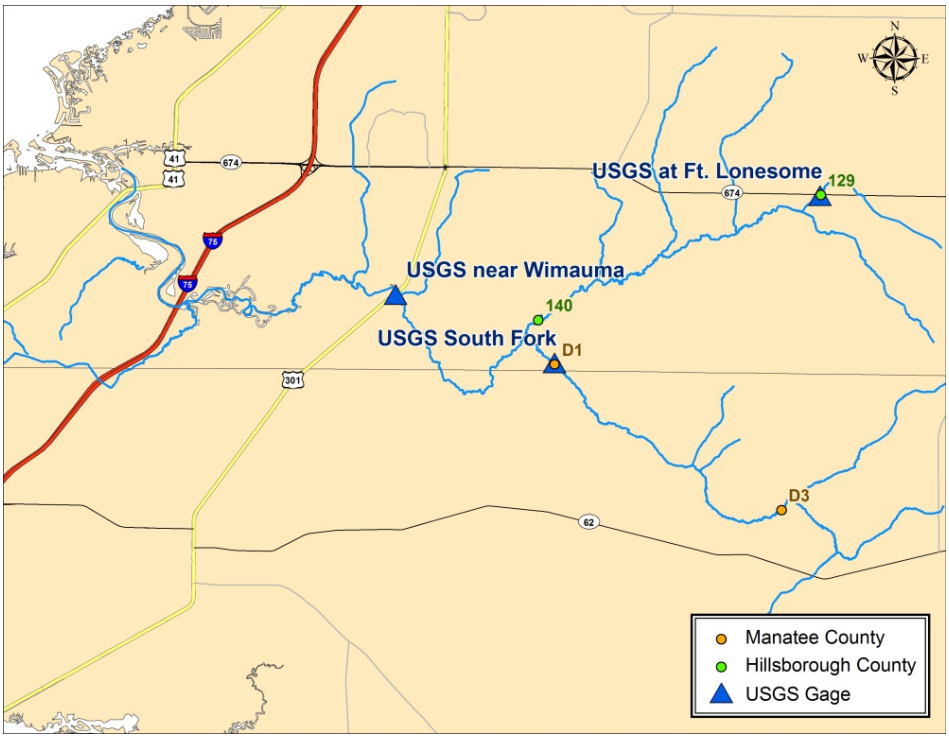

Figure 10. Location of active long-term water quality monitoring sites selected for analysis above US301 in the Little Manatee River.

Results of the Seasonal Kendall Tau trend test for the EPC stations are provided in Table 7. The only difference in results between tests conducted prior to, and after, adjusting for the effects of flow (using the USGS 02300100 - Fort Lonesome discharge values) was dissolved oxygen percent saturation at Station 140 where, after accounting for the effects of flows, the trend results changed from Decreasing to No Trend. Of the significant trend results, most constituents would be considered to be improving over time (e.g. decreasing concentrations of nutrients). The exceptions were increasing trends in organic nitrogen concentrations and an increasing trend in fluoride at station 129.

The results of the log-transformed linear regression analysis are also provided in Table 7 with statistically significant results (i.e. a p value for the flow term < 0.05) indicated by a positive or negative 1. The sign of the value indicates the direction of the trend result. Most of the water quality constituents exhibited a statistically significant relationship with flows. Positive relationships with flow at both stations included total and orthophosphorus, fluoride, fecal coliforms, organic nitrogen and turbidity. Negative relationships with flow at both stations included chlorophyll *a*, dissolved oxygen, nitrate/nitrite, and pH. Detailed linear regression output for these stations can be found in the supplemental materials document accompanying this memorandum.

Table 7. **Results of Seasonal Kendall Tau test for trend and linear log-log regression ("Regression Results") for stations 129 and 140 in the mainstem of the Little Manatee River above US301.**

Water Quality Constituent	Station	Start Year	End Year	# of Samples	Trend Direction	Flow Adjusted Trend Direction	Regression Results
Chlorophyll *a* (ug/l)	129	1976	2019	381	No Trend	No Trend	-1

Results for the two Manatee County stations in the South Fork of the Little Manatee are provided in Table 8. BOD and dissolved oxygen (% saturation) were increasing at both stations over time and not effected by flow after accounting for seasonality. The pH trends were decreasing at both stations over time. The remaining trends were either stable (i.e. No Trend) or site specific. Detailed linear regression output for these stations can be found in the supplemental materials document accompanying this memorandum.

Table 8. **Results of Seasonal Kendall Tau test for trend and linear log-log regression ("regression results") for stations D1 and D3 in the South Fork of the Little Manatee River above US301.**

Summary and Recommendations:

The results of analyses presented in this technical memorandum largely agree with previous findings. According to DEP's latest assessment (July 2020), the Little Manatee River remains in compliance with state water quality standards for water quality parameters other than fecal coliform. Trends in water quality are generally improving though site specific instances of increasing trends were identified. Four stations upstream of US301 maintain active water quality sampling providing additional information on water quality in the upstream portion of the system. Many of these constituents had statistically significant relationships with flow independent of seasonality. However, as described in the following paragraphs, there are limitations of this analysis in consideration of using water quality as a WRV consistent with the Water Resource Implementation Rule 62-40, Florida Administrative Code (FAC).

The Seasonal Kendall Tau trend test provides a statistical evaluation of a change in a particular water constituent over time but is not an explanatory model. That is, the test does not determine

why the trend over time may exist. Residualizing the data against flow prior to conducting Seasonal Kendall Tau is an attempt to determine if there is a change in the water quality parameter over time after accounting for the relationship between water quality and flow. In many cases, the water quality constituent had both a change associated with flow and a change associated with time indicating other unexplained factors in addition to flow were contributing to a change in the constituent over time.

The flow adjustment was performed using LOESS regression which is a nonparametric smoothing technique used in the original effort to capture potential nonlinear relationships with flow. Since that time, the District has identified natural log transformations as a parametric alternative statistical technique to identify relationships between water quality constituents and flow. The regression results reported in the tables using 0, -1, or 1 are based on the log-log linear regression results.

When a large proportion of values associated with a water quality constituent are reported at their detection limit, this can affect both the timeseries trend tests and the regression results. In both cases, the tests will be reduced in power. Constituents including BOD, chlorophyll and ammonia may have suffered from this artifact. These effects can be seen in the timeseries plots provided in the supplemental materials document.

Finally, streamflow is the product of interactions between rainfall, soil characteristics, storage in the watershed, antecedent conditions, and the effects of both natural and anthropogenic land use changes. Thereby, seasonality in rainfall, which is correlated with temperature, drives both streamflows and changes in water quality. Therefore, while relationships may be present between flows and water quality, it is inappropriate to assign causality to flows as a direct effect based solely on these statistical outcomes. The outcomes suggest that the hypothesis being tested was either rejected or failed to be rejected but the inference from the statistical outcomes must be conveyed within the context of a weight of evidence to determine if the relationship should be used when considering water quality as a water resource value associated with rule 62-40 F.A.C.

This document contains hyperlinks to associated pages in portable document format (pdf) containing detailed descriptive statistics, plots, and results of statistical analysis. The document is organized by source, station and parameter. Hyperlinks to individual output are described below.

1) EPC station data. These pages contain descriptive statistics and plots for each station with at least 30 observations organized by source and include:
    a. Summary tables of number of observations, sampling period of record and outliers identified using Robust Regression, distribution percentiles, and values deviating by more than three standard deviations from the log normal means. Organized by station.
    b. Univariate histograms organized by water quality constituent including descriptive statistics
    c. Seasonality plots organized by water quality constituent using monthly box and whisker plots
    d. Timeseries plots organized by parameter with outliers identified for each of the three outlier methods described.
    e. Downstream log log linear regression results for EPC station from US301 to the mouth
    f. Upstream log log linear regression results for EPC stations 140 and 129 above US301

2) IWR station data. These pages contain descriptive statistics and plots for each station with at least 30 observations organized by source and include:
    a. Summary tables of number of observations, sampling period of record and outliers identified using Robust Regression, distribution percentiles, and values deviating by more than three standard deviations from the log normal means. Organized by station.
    b. Univariate histograms organized by water quality constituent including descriptive statistics
    c. Seasonality plots organized by water quality constituent using monthly box and whisker plots
    d. Timeseries plots organized by parameter with outliers identified for each of the three outlier methods described.
    e. Linear (log log) regression results for Manatee County stations D1 and D3 in the South Fork of the Little Manatee River.

EPC_LMR             Water quality data from Hillsborough County
                    EPC data set for Stations 112,113 , 129, 140, 180, 181,and 182
                    on the Little Manatee River.

LMR_UpStr301_IWR59  Water quality data from the IWR database (Run 59).
                    These water quality stations are above US-301
                    on the Little Manatee River and include  EPC, USGS and other entitiy data collections.

USGS_02300100       USGS Streamflow station 02300100
                    LITTLE MANATEE RIVER NEAR FT. LONESOME FL
                    Has daily Discharge, gage height, and Water
                    surface elevation starting February 1964.

USGS_02300300       USGS Streamflow station 02300300
                    SOUTH FORK LITTLE MANATEE RIVER NEAR WIMAUMA FL
                    Has daily Discharge, gage height, rainfall, and Water
                    surface elevation starting October 1987.

USGS_02300500       USGS Streamflow station 02300500
                    LITTLE MANATEE RIVER AT US 301 NEAR WIMAUMA, FL
                    Has daily Discharge, gage height, rainfall,
                    Specific Conductance, and Water surface elevation
                    starting April 1939.
